

CURS 1

Sistem de operare = program care actua ca un intermediu între utilizator și hardware-ul computerului

Computer System

- hardware
- OS → allocates resources
- apps.
- Users. (can be other machines too)

BOOTSTRAP → loaded on power-up or reboot

(Firmware) → typically stored in ROM

→ initializes all aspects of system

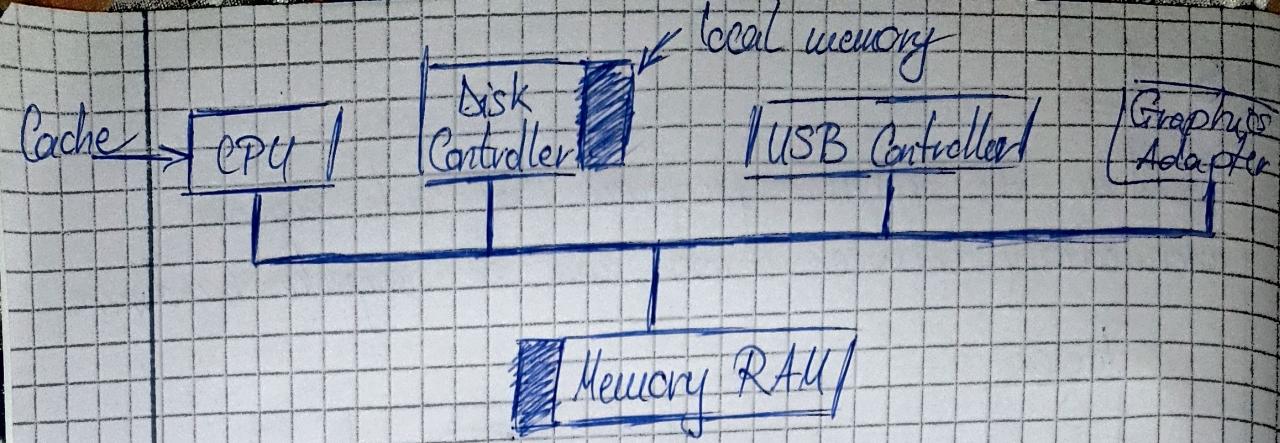

→ loads kernel

BOOTLOADER checks which OS is installed.

One or more PCI's, device controllers connect through **BUS** providing access to shared memory.

există un controller în memorie care se ocupa de management-ul memoriei

⇒ BUS-ul e la vîrsta procesorului

- CPU and I/O devices can run simultaneously because they have a **LOCAL BUFFER**
- Device controller informs CPU that it has finished its operation by causing an **INTERRUPT**
Interrupt transfers control to the interrupt service routine generally through the **INTERRUPT VECTOR** which contains addresses of all service routines
- if **TRAP/EXCEPTION** is a software generated interrupt caused either by an **ERROR** or a **USER REQUEST**

An OS is **INTERRUPT DRIVEN**

Type of interruptions ↗ **POLLING** (inefficient & slow if many)
↗ **VECTORED INTERRUPT SYS**

CURS 2

Fisicale suni stoate in SSD si' devin procese in RAM

I/O Structure

After I/O starts, control returns to user program
only upon I/O completion

OR

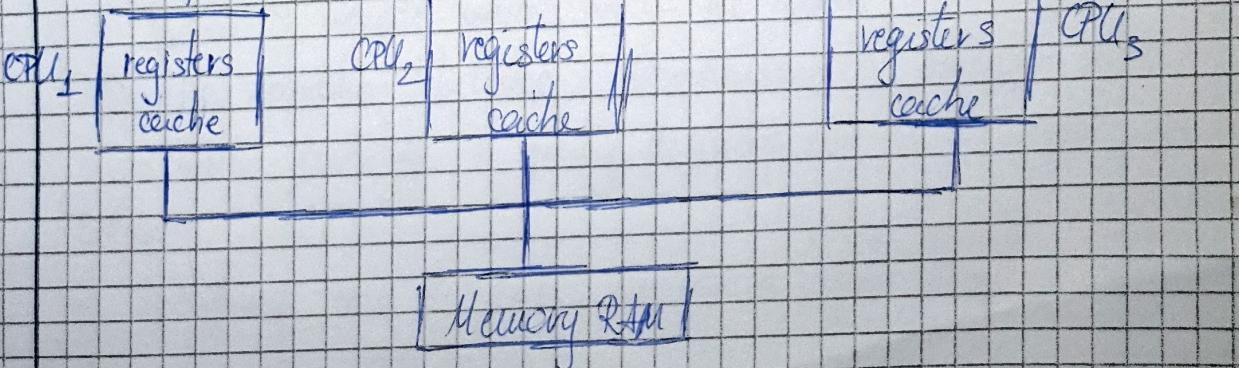

without waiting for I/O completion

Storage Device Hierarchy

Multiprocessors

↳ Asymmetric Multiprocessing
= each processor is assigned a specific task

↳ Symmetric Multiprocessing
= each processor all tasks

FROM USER TO KERNEL

Timer to prevent infinite loop.

- timer is set to interrupt the computer after some time
- timer is set by OS
- when counter = 0 \Rightarrow causes an interrupt
- set up before scheduling process to regain or terminate program that exceed allotted time

If **PROCESS** is a program in execution. It is a unit of work within the system. Program is a **PASSIVE ENTITY**, process is an **ACTIVE ENTITY**.

Process termination requires release of any reusable resources

Single threaded process has one **PROGRAM COUNTER** specifying the location of next instruction to execute

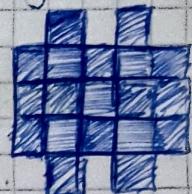

Multi-threaded process has one program counter per thread

CERS 3

Each system call is associated with a number

- system-call interface maintains a table indexed according to these numbers

The system call interface invokes the intended system call in OS Kernel \Rightarrow returns the status of the system call

System Call Parameters Passing

- pass parameters in registers
- parameters stored in a block or table in memory and address of block is passed as a parameter in a register
- parameters placed, or PUSHED onto the stack by the program and POPPED off the stack by the operating system

Block and stack methods do not limit the number or length of parameters being passed

OS Design & Implementation

Mechanisms determine how to do something

Policies decide what will be done

The separation between Mechanism & Policies allows maximum flexibility if policy decisions are to be changed later

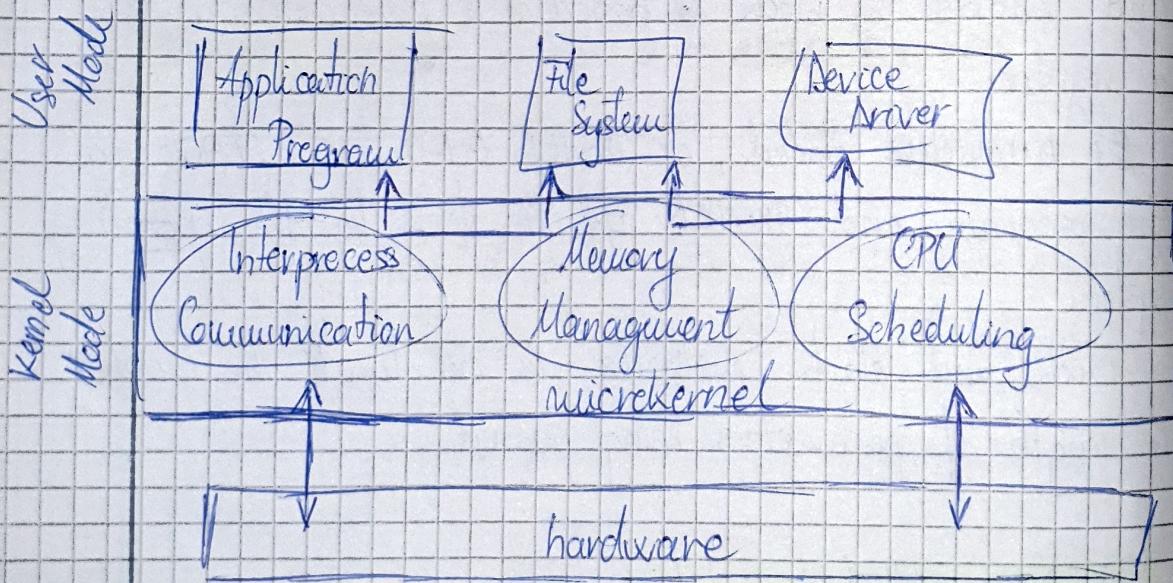

Specifying and designing an OS is highly creative task of software engineering.

EMULATION can allow an OS to run on non-native hardware

The OS is divided into a number of layers. With modularity, layers are selected such that each uses functions (operations) and services of only lower-level layers.

MICROKERNEL

Moves as much from the Kernel into user space
Communication takes place between user modules using MESSAGE PASSING

HYBRID SYSTEMS

They combine multiple approaches to address performance, security, usability needs

SYSGEM program contains information concerning the specific configuration of the hardware system
Used to build system-specific compiled kernel or system-tuned

SYSTEM BOOT

- Firmware ROM used to hold initial boot code
- OS must be made available to hardware so hardware can start it

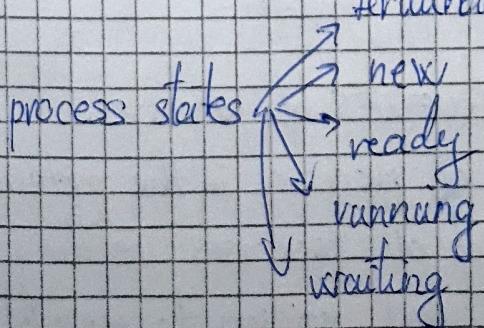

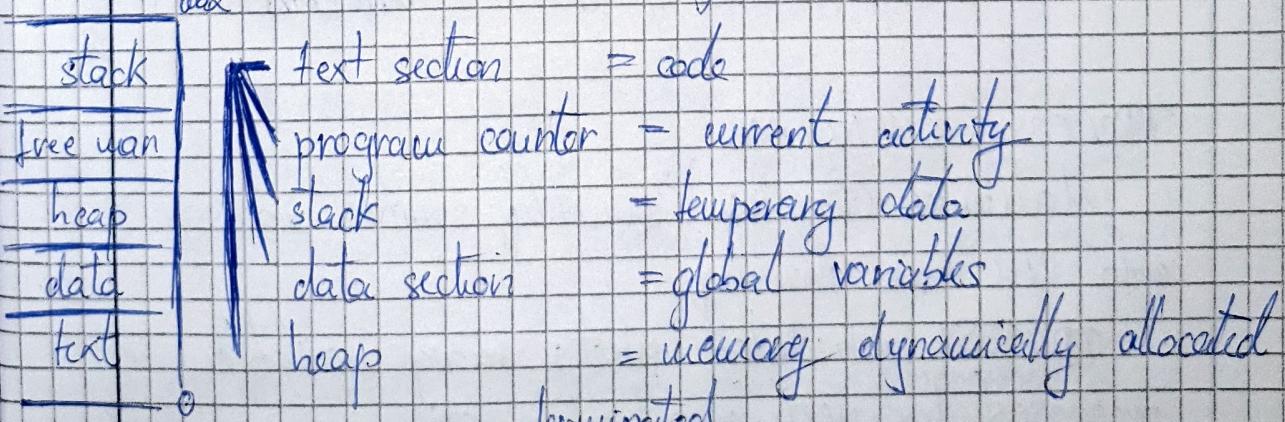

CURS 4

PROCESSES

An OS executes

- batch systems = jobs
- time-shared systems = user prog.

PROCESS = a program in execution; process must progress in sequential ~~action~~ fashion

PROCESS CONTROL BLOCK

TASK CONTROL BLOCK

process state	
process number	→ location of the next instr. to exec.
program counter	
registers	→ contents of all process specific registers
memory limits	→ memory allocated to the process
list of open files	
accounting information	= CPU used, clock time elapsed since start, time limits

THREADS

A process has a single **thread of execution**

multiple program counters/process

⇒ multiple locations can execute at once

⇒ multiple threads of control → **THREADS**

PROCESS SCHEDULING

Maximize CPU use, quickly switch processes onto CPU time sharing

PROCESS scheduler selects among available processes for next execution on CPU

Maintains **SCHEDULING QUEUES** of processes

- job queue → set of all processes in the system
- ready queue → set of all processes residing in main memory, ready and waiting to execute

- device queues → set of processes waiting for an I/O device
- Processes migrate among the various queues

CURS 5

at process cannot access the memory address of another process

- Sistemul de operare dă cumpăra procesului că totălă memoria este pentru el

PROCESS CREATION

Parent process creates CHILDREN PROCESSES which in turn create other processes, forming a tree of processes

Processes identified and managed via PID
(process identifier)

- ☒ Parent and Children share all resources
- ☒ Children share subset of parent's resources
- ☒ Parents & children share no resources

RESOURCE SHARING

EXECUTION PRIORITIES

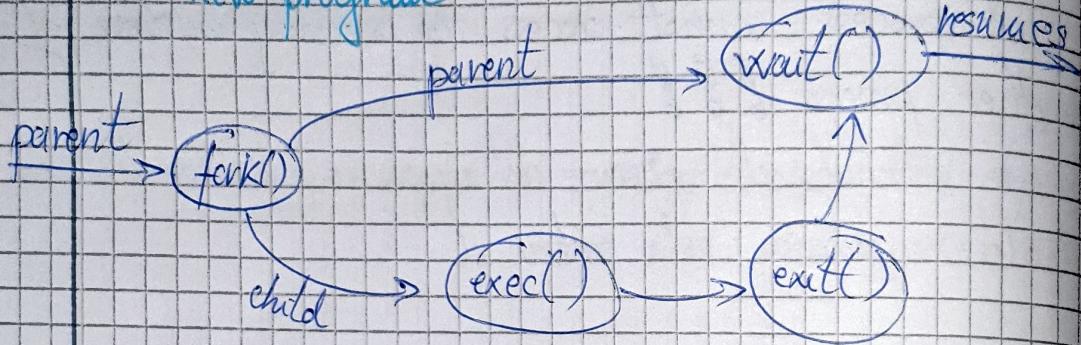

ADDRESS SPACE

- Child duplicate of parent
- Child has a program loaded onto it

`fork()` → system call creates new process

`exec()` → system call used after `fork()`

to replace the process' memory space with a new program

PROCESS TERMINATION

Process executes last statement and then asks the OS to delete it using `exit()`

- Returns status data from child to parent (via `wait()`)
- Process' resources are deallocated by OS
- Parent may terminate the execution of children processes using the `abort()` sys call
- child has exceeded allocated resources
- Task assigned to child is no longer required
- The parent is exiting and the OS does not allow a child to continue if its parent terminates

Solve SC don't allow child to exist if its parent has terminated. If a process terminates, then all its children must also be terminated.

■ cascading termination: All children, grandchildren are terminated

■ the termination is initiated by the OS

The parent process may wait for the termination of child process by using the `wait()` sys call. The call returns status info and the PID of the terminated process

→ `pid = wait(2 stdio)`

If NO parent waiting (didn't invoke `wait()`)
⇒ zombie process

If parent terminated without invoking `wait()`
⇒ orphan process

If one web tab causes trouble ⇒ entire browser can crash

INTERPROCESS COMMUNICATION

Process within a system may be $\xrightarrow{\text{INDEPENDENT}}$ $\xrightarrow{\text{COOPERATING}}$

Cooperating process can affect or be affected by other processes including SHARING DATA

Cooperating processes need IPC (interprocesses communication)

IPC $\xrightarrow{\text{shared memory}}$

message passing

Advantages: modularity

PRODUCER PROCESS produces info that is consumed by a CONSUMER PROCESS

- Unbounded-buffer = places NO practical limit on the size of the buffer
- bounded-buffer = assumes that there is a fixed buffer
- shared memory solution

SHARED MEMORY MESSAGE PASSING

An area of process to communicate and to sync their actions

Message System = processes communicate with each other without resorting to share variables
IPC facility provides operations → SEND / RECEIVE

The message size is either
fixed or variable

If process P & Q wish to communicate
steps
→ establish a communication link
→ exchange messages (send/receive)

Implementation of Communication link

→ physical
→ shared memory
→ hardware bus
→ network

→ logical → direct or indirect

- communication links are established automatically
 - can be associated with exactly one pair of communication processes
- each pair of processes may share multiple communication links

SYNCHRONIZATION

Message passing may be either blocking OR non-blocking

BLOCKING → synchronous

blocking send → the sender is blocked until the message is received

blocking receive → the receiver is blocked until a message is received

NON-BLOCKING → asynchronous

non-blocking ^{sends} → the sender sends the message and continues

non-blocking receive → the receiver receives NULL or a valid message

If blocking and receive we have rendez-vous

CURS 6

Message passing centric via ADVANCED LOCAL PROCEDURE CALL (ALPC) facility

► Only works between processes of the same system

► Uses ports to establish and maintain communication channels

SOCKETS

A SOCKET is defined as an endpoint for communication

• Communication consists between a pair of sockets

• host : port

REMOTE PROCEDURE CALLS

Data representation handled via External Data Representation (XDR) format to account for different architectures

► big-endian : MS bit

► little-endian : LS bit

Remote communication has more failure scenarios than local

► Messages can be delivered exactly once rather than at most once

OS typically provides matchmakers service to connect client and server

PIPES

Acts as conduit allowing 2 processes to communicate

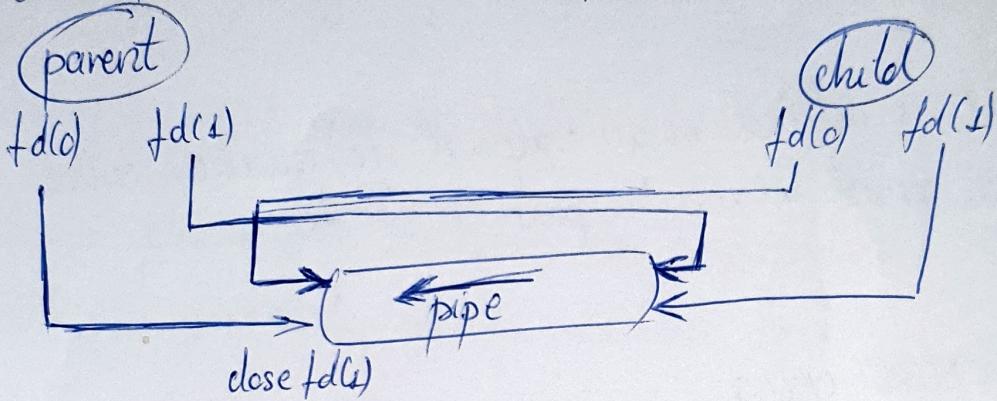

ORDINARY PIPES - cannot be accessed from outside the process that created it. If a parent process creates a pipe and uses it to communicate with a child process that it created
NAMED PIPES - can be accessed without a parent-child relationship

ORDINARY PIPES

allow communication in standard - ^{producer} consumer style
Producer writes to one end and consumer reads from the other end.

Ordinary pipes are therefore unidirectional

Require parent-child relationship between communicating processes

NAMED PIPES

are more powerful than ordinary pipes

Communication is bidirectional

NO parent-child relationship is required

Several processes can use the named pipe for communication

MULTICORE PROGRAMMING

types of parallelism

DATA PARALLELISM - distributes subsets of the same data across multiple cores, same operation on each

TASK PARALLELISM - distributing threads across cores, each thread performs unique operation

as the number of threads grows, so does architectural support for threading

CURS 7

AMDAHL'S LAW

Identifies performance gains from adding cores to an app that has both serial and parallel components

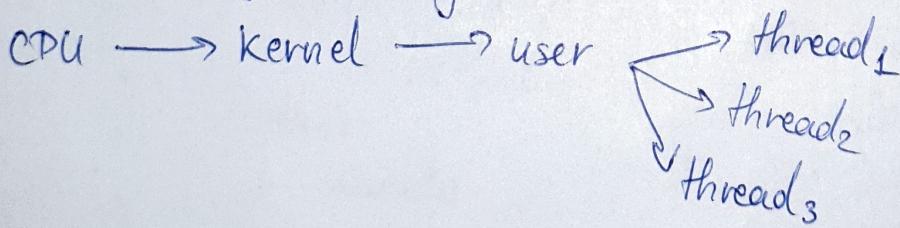

$$\text{speedup} \leq \frac{1}{S + \frac{1-S}{N}} ; \quad S - \text{serial portion} \\ N - \text{processing cores}$$

as $N \rightarrow \infty \Rightarrow \text{speedup} \rightarrow \frac{1}{S}$

Serial portion of an application has disproportionate effect on performance gained by adding additional cores

MANY-TO-ONE threads mapped to a single Kernel thread.

- one thread blocking causes all to block
- multiple threads may not run in parallel on multicore sys because only one may be in kernel at a time

ONE-TO-ONE

- each user-level thread maps to kernel thread
- creating a user-level thread creates a kernel thread
- more concurrency than many-to-one
- ~~the~~ number of threads / process sometimes restricted due to overhead

MANY-TO-MANY allows many user level threads to be mapped to many kernel threads
- allows the OS to create a sufficient number of kernel threads

THREAD LIBRARY → for API

PThreads may be provided either as user-level or kernel-level

CRITICAL SECTION PROBLEM

Each process has a CRITICAL SECTION segment of code
☒ process may be changing common variables, updating tables etc
☒ when one process is in critical section, no other may be in its critical section

Critical section problem is to design protocol to solve this

Each process must ask permission to enter critical section in ENTRY SECTION, may follow critical section with EXIT SECTION then REMAINDER SECTION

```
do {  
    entry section  
    critical section  
    exit section  
    remainder section } while (true);
```

SYNCHRONIZATION HARDWARE

Many systems provide hardware support for implementing the critical section code.

idea of locking: protecting critical regions via locks

Uniprocessors - could disable interrupts

- currently running code would execute without preemption
- generally too inefficient on multiprocessor sys

lock \Rightarrow actions become atomic operations
 \rightarrow cannot be interrupted

\hookrightarrow check if there is access to the variable which shows if the operation is locked or not

MUTEX LOCKS = protect a critical section by first acquire() a lock and then release() the lock

- boolean variable to indicate if the lock is available or not
- acquire() & release() are atomic
- this solution requires BUSY WAITING \rightarrow lock is called SPINLOCK

do {
 acquire lock()
 critical section
 release
} remainder

} HARDWARE SOLUTION

SEMAPHORE = sync tool that provides more sophisticated ways for processes to sync their activities

- can only be accessed via two invisible(atomic) operations wait(); signal()

DEADLOCK & STARVATION

DEADLOCK = 2 or more processes are waiting indefinitely for an event that can be caused by only one of the waiting process

STARVATION - INDEFINITE BLOCKING

A process may never be removed from the semaphore queue in which it is suspended

PRIORITY INVERSION = scheduling problem when lower-priority process hold a lock needed by higher-priority process

solution: priority-inheritance protocol

↳ PETERSON

- syncs 2 processes
- the 2 processes have 2 variables in common
 - turn: index which describes which process is in the critical condition
 - flag: shows which process waits in line for to enter the critical condition

do

```
{ flag[i] = TRUE;  
turn = i;  
while (!flag[j] && turn == j)  
    //critical section
```

```
    flag[i] = FALSE  
    //remainder section } while (TRUE);
```

} SOFTWARE SOLUTION

CURS 9/

MONITORS - SOLUTION FOR SEMACOCKS

↳ of high-level abstraction that provides a convenient & effective mechanism for process sync

- ABSTRACT DATA TYPE → internal variables only accessible by code within the procedure

- only 1 process may be active within the monitor at a time

- monitor is not powerful enough to model some sync schemes

condition $x.y;$

$x.wait();$ → a process that invokes the operation is suspended until $x.signal()$

$x.signal()$ → resumes one of the processes that called $x.signal()$

options ↳ SIGNAL & WAIT = P waits until Q leaves the monitor or for another condition

SIGNAL & CONINUE = Q waits until — ↳

```
{ wait(counter)
  ||
  body of F
  ||
  if(next-count > c)
    signal(next)
  else signal(counter); }
```

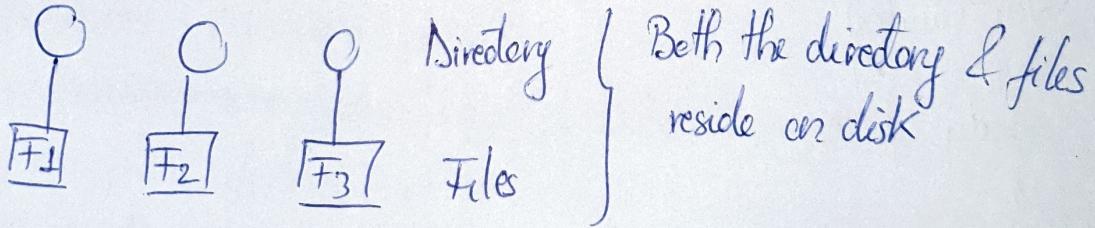

CURS 10

OPEN FILES → file-open count = counter of number of times a file is open to allow removal of data from open-file table when last process closes it

OPEN FILE LOCKING

- SHARED LOCKS → several processes can acquire concurrently
 - similar to reader lock
- EXCLUSIVE LOCK → similar to writer lock
- MANDATORY → access is denied depending on locks held and requested
- ADVISORY → processes can find status of locks and decide what to do.

DIRECTORY STRUCTURE

TREE STRUCTURED DIRECTIONS

- path
- ABSOLUTE: from source
 - RELATIVE: from current folder

FILE SYSTEM MOUNTING

A file system must be mounted before it can be accessed. An unmounted file system is mounted at mount point

REMOTE FILE SYSTEMS

Uses networking to allow file system access between systems

- manually via programs
- automatically via DISTRIBUTED FILE SYSTEMS
- semi-automatic via WORLD WIDE WEB

CLIENT SERVER model allows clients to mount remote file systems from servers

DISTRIBUTED INFORMATION SYSTEMS (DIRMING SERVICES) such as Active directory implement unified access to info needed for remote computing

FILE SYSTEMS - FAILURE MODELS

~~DATA LOSS~~ corruption of directory structures or non-user data
Recovery from failure can involve STATE INFORMATION about status of each remote request

STATELESS PROTOCOLS such as NFS v3 include all info in each request, allowing easy recovery but less security

CURS 11

PARTITIONS & MOUNTING

Partition can be a volume containing a file system or RAW - just a sequence of blocks with no file system

Boot Block can point to a boot volume/loader set of blocks that contain enough code to know how to load the kernel from the file system

ROOT PARTITION contains the OS, other partitions can hold other OSs
↳ mounted at boot time
↳ other partitions can mount automatically or manually

DIRECTORY IMPLEMENTATION

LINEAR LIST of file names with pointer to data blocks
↳ simple to code
↳ time-consuming

HASH TABLE - linear list with hash data structure
↳ decreases directory search time

↳ collisions - situations where 2 file names hash to the same location

↳ good if entries are fixed size or use chainsaw-overflow method

ALLOCATION METHODS - how disk blocks are allocated to files
CONTIGUOUS ALLOCATION - each file occupies set of contiguous blocks

LINKED ALLOCATION - each file a linked list of blocks

→ file ends at NIL POINTER

→ NC external fragmentation

→ improve efficiency by clustering blocks into groups but increases internal fragmentation

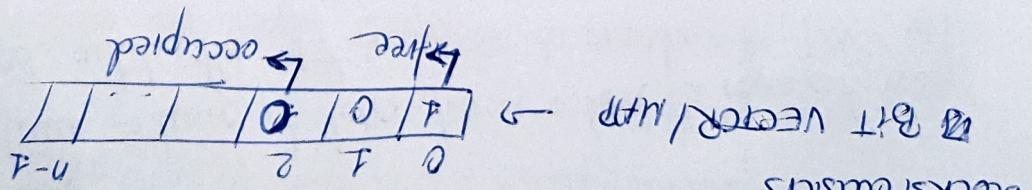

→ FAT (File Allocation Table)

INVERSE ALLOCATION - each file has its own index of blocks of pointers to its data blocks

PETRICENCE

FREE SPACE MANAGEMENT

File system maintains FREE SPACE LIST to track available blocks/devices

blocks/devices

FREE SPACE MANAGEMENT

CPU BURST distribution is of main concern
↳ load > slice
↳ read full

CWRS 12 /

SCHED-TIME SCHEDULE selects from among the processes in ready queue and allocates CPU to one of them
CPU SCHEDULE
NO PREEMPTION
all other scheduling is PREEMPTIVE
slices: 1 running \rightarrow ready
waiting \rightarrow ready
returnables
all other scheduling is PREEMPTIVE
DISPATCHER module gives control of the CPU to the process selected by short term scheduler
→ switch context
→ switch to user mode
→ unwinding to the program location in the user program
→ restart the program

DISPATCH LATENCY = time for the dispatcher to stop a process and start another one (more like "freeze")

SCHEDULING CRITERIA

- MAX {
- CPU usage
 - throughput \rightarrow #processes that complete their exec/time unit
- MIN {
- turnaround time \rightarrow time to execute a particular process
 - waiting time \rightarrow
 - response time \rightarrow time it takes from when a request was submitted until the 1st response is produced (UI, UX)

FCFS SCHEDULING - First Come First Served

CONVOY EFFECT - short process behind long process.

SJF SCHEDULING - Shortest Job First

Gives the minimum average waiting time for a set of processes.

- associate with each process the length of its next CPU burst
↳ is priority scheduling where priority is the inverse predicted next CPU burst time

DETERMINING LENGTH OF NEXT CPU BURST

t_n - actual length of n^{th} CPU burst

t_{n+1} - predictive value

$$0 \leq \alpha \leq 1 \Rightarrow t_{n+1} = \alpha t_n + (1-\alpha) t_n$$

↳ usually set to $\frac{1}{2}$

Preeptive version called SHORTEST REMAINING TIME FIRST

problem = STARVATION - low priority processes may never execute

solution = AGING - as time progresses increases the priority of the process

ROUND ROBIN (RR)

Each process gets a small unit of CPU time (TIME QUANTUM q) usually 10-100 ms. After this time has elapsed, the process is preempted and added to the end of the ready queue (RQ).

If there are n processes in the RQ and $q \rightarrow$, each process gets $1/n$ of the CPU time in chunks of at most q time units at once. No process waits more than $(n-1)q$ time units.

q large \Rightarrow FIFO

q small $\Rightarrow q$ must be large to respect the context switch

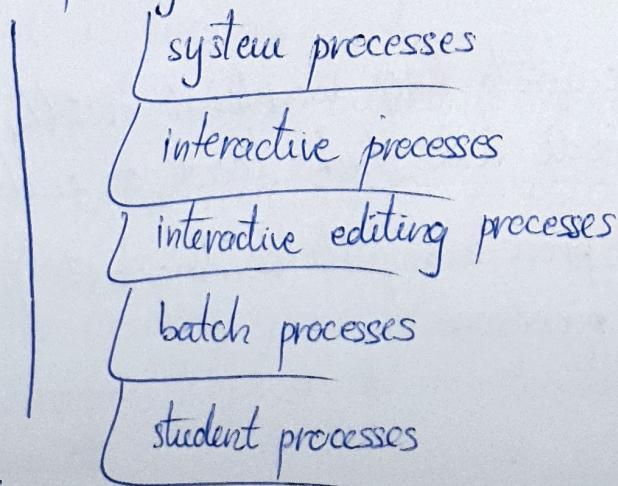

$q >$ CONTEXT SWITCH

MULTILEVEL QUEUE

ready queue $\xrightarrow{\text{FOREGROUND}} \text{RR} \text{ (interactive)}$
 $\xrightarrow{\text{BACKGROUND}} \text{FCFS} \text{ (batch)}$

each queue has its own scheduling programme alg.

highest priority

lowest priority

THREAD SCHEDULING

- distinction between user-level and kernel level threads
 - many-to-one
 - many-to-many
- ~~thread library~~
- ↳ run on LWP - process-contention scope
(PCS) = competition among all threads

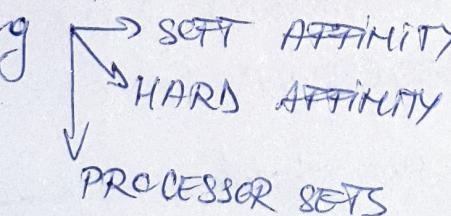

MULTI-PROCESSOR SCHEDULING

HOMOGENEOUS PROCESSORS

ASYMMETRIC MULTIPROCESSING = only 1 processor accesses the system data structures

SYMMETRIC PROCESSING (SMP) = each processor is self-scheduling all processes in common ready queue or each one has its own private ready queue

PROCESSOR AFFINITY - process has affinity for processor on it is currently running

SMP

- LOAD BALANCING - attempts to keep workload evenly distributed
- PUSH MIGRATION - periodic task checks load on each processor
- PULL MIGRATION - idle processors pulls waiting task from busy processor

CURS 13

LOGICAL vs PHYSICAL ADDRESS SPACE

Logical address space that is bound to a separate PHYSICAL ADDRESS SPACE is central to proper memory management.

↳ LOGICAL ADDRESS - generated by the CPU (VIRTUAL ADDRESS)
↳ PHYSICAL ADDRESS - address seen by the memory unit

- they are the same in compile-time address-binding schemes
- ≠ execution-time

LOGICAL ADDRESS SPACE = set of all logical addresses generated by the program

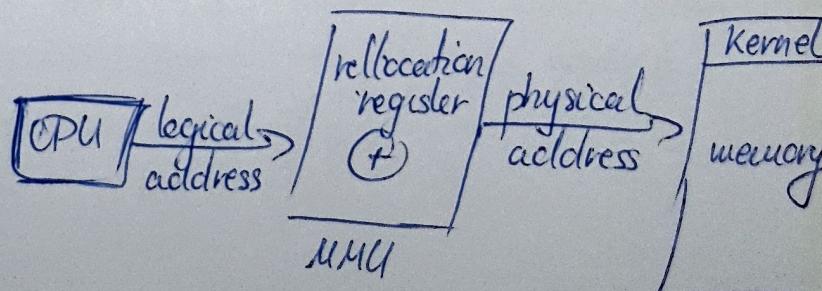

PHYSICAL ADDRESS SPACE = — u — physical — u —

MEMORY-MANAGEMENT UNIT (MMU)

- hardware device that at run time maps virtual to physical address.
- the user program deals with logical addresses
 - ↳ exec. time binding occurs when reference is made to location in memory
 - ↳ logical address bound to physical addresses

DYNAMIC RELOCATION USING A RELOCATION REGISTER

- routine is not loaded until is called
- better memory space utilization
- all routines kept on disk in relocatable load format

DYNAMIC LINKING

STATIC LINKING = sys libraries & program code combined by the loader into the binary program image

DYNAMIC LINKING = linking postponed until execution time

STUB = small piece of code used to locate the appropriate memory resident library routine
↳ replaces itself with the address of the routine & executes the routines

system also known as SHARED LIBRARIES

MULTIPLE PARTITION ALLOCATION

- degree of multiprogramming limited by num. of partitions

- VARIABLE PARTITIONS sizes of efficiency

- HOLE - block of available memory

→ when a process arrives, it is allocated memory from a hole large enough to accommodate it

→ existing process frees its partition, adj free partitions combined

→ OS maintains ↗ allocated partitions
 ↘ free — — —

DYNAMIC STORAGE-ALLOCATION PROBLEM

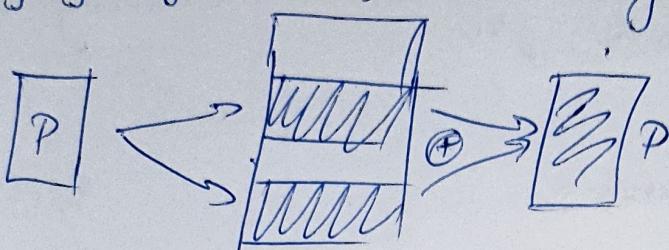

☒ FIRST-FIT : first hole big enough

☒ BEST-FIT : allocate the SMALLEST hole that is big enough

☒ WORST-FIT : allocate the LARGEST hole

FRAGMENTATION

- EXTERNAL FRAGMENTATION = total memory space to satisfy a request
- INTERNAL FRAGMENTATION = allocated memory may be slightly larger than requested memory

SEGMENTATION ARCHITECTURE

SEGMENT TABLE = maps 2-dimensional physical addresses (PA)

↳ BASE = contains the starting PA

↳ LIMIT = length of the segment.

SEGMENT-TABLE BASE REGISTERS (STBR) = points to the segment table's location in memory

— LENGTH — (STCR) = indicates the number of segments from the program

segment-num < STCR !

PAGING

Process is allocated physical memory whenever the latter is available
divide physical memory into fixed-sized blocks called FRAMES

logical — blocks of the same size called PAGES

Set up a PAGE TABLE to translate logical \rightarrow physical address
- still have internal fragmentation

ADDRESS TRANSLATION SCHEME

PAGE NUMBER (p) = used as an index into PAGE TABLE which contains base address of each page in PHYSICAL MEMORY

PAGE OFFSET (o) = combined with base address to define the physical memory address that is sent to the memory unit

LOGICAL ADDRESS SPACE = 2^m

PAGE SIZE 2^n

IMPLEMENTING OF PAGE TABLES

Page table is kept in main memory

PAGE-TABLE BASE REGISTER (PTBR) - points to the page table

— — LENGTH — — (PTLR) - size of the page table

Every data access requires 2 memory accesses

The two memory access problem can be solved by the use of a special fast-lookup hardware cache called ASSOCIATIVE MEMORY OR TRANSLATION LOOK-ASIDE BUFFERS (TLBS)

EFFECTIVE ACCESS TIME (EAT)

$$EAT = (1 + \epsilon)L + (2 + \epsilon)(1 - L) = L + \epsilon - L\epsilon$$

ϵ = time unit

L = hit ratio = % of times that a page number is found in the associative registers

MEMORY PROTECTION - associate protection bit with each frame to indicate if RO or RW access is allowed

VALID-INVALID Bit \rightarrow VALID \Rightarrow the associated page is in the process logical Address space

INVALID = — a — is not — a —

OR use

PTQ
